## 1. Theoretical questions ( $\mathbf{1 2}$ points)

1.1. Give the formal definition of a Kripke structure! Describe the basic difference between a Kripke structure and a labeled transition system (LTS)!
,
A Kripke structure $K S$ over a set of atomic propositions $A P=\{P, Q, R, \ldots\}$ is a tuple $(S, I, R, L)$ where

- $S=\left\{s_{1}, s_{2}, \ldots, s_{n}\right\}$ is a finite set of states,
- $I \subseteq S$ is the set of initial states,
- $R \subseteq S \times S$ is the set of transitions and
- $L: S \rightarrow 2^{A P}$ is the labeling of states by atomic propositions

The basic difference is that in Kripke structures, we label states (with zero or more atomic propositions), while in LTSs, we label transitions with exactly one action.
1.2. Describe the most important restrictions (constraints) in CTL compared to CTL*! Give an example formula that is a valid CTL* expression but not a valid CTL expression!

3 points
In CTL, operands are composed of exactly one path quantifier and one temporal operator (connective).
Example: EXXp (not CTL because of XX).
1.3. How can we reach a contradicting branch when using the tableau decomposition method for PLTL model checking and applying the decomposition rules for 1) operator X 2) and operator $\mathbf{U}$ ?

1. $(X, U)$ : atomic propositions contradict each other or the labeling of the state
2. (X,U): there is no next state
3. (U): loop of $p$ without $q$.
1.4. Describe the basic idea of bounded model checking (BMC) and describe with a flow chart how to use it in an iterative strategy to cover the state space up to a given bound!

By using characteristic functions, describe a path of length $k$ leading to a state that violates the invariant to check. Look for a satisfying model with a SAT solver. If a model is found, it induces a counterexample, otherwise the bound $k$ should be increased.

2.1. Give the reduced ordered binary decision diagram (ROBDD) representation of the function $f$ given by the truth table below! Use the variable order $x, y, z$ in the ROBDD representation!

| $\boldsymbol{x}$ | $\boldsymbol{y}$ | $\boldsymbol{z}$ | $\boldsymbol{f}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z})$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 1 |
| 0 | 0 | 1 | 0 |
| 0 | 1 | 0 | 0 |
| 0 | 1 | 1 | 1 |
| 1 | 0 | 0 | 1 |
| 1 | 0 | 1 | 1 |
| 1 | 1 | 0 | 0 |
| 1 | 1 | 1 | 1 |

2.2. There is exactly one node missing from the dotted rectangle in the ROBDD above. (Note that this ROBDD is not related to the function $f$ in the previous subtask.) Which variable(s) may belong to this missing node? For each possible variable, give the algebraic form of the function described by the ROBDD!

Only $y$ is good, because otherwise the node would be identical to the other $z$ node.
Algebraic form: $(x \wedge y) \vee(x \wedge \neg y \wedge z) \vee(\neg x \wedge y)$
2.3. Select one of the possible functions from the previous subtask (2.2) and denote this function by $g$. Compute the ROBDD representation of the function $f \vee g$ ! Perform the computation directly using the ROBDD operations on $f$ and $g$ (OR operation)! Use the same variable order as before $(x, y, z)$ ! $\qquad$

## 3. Symbolic model checking (8 points)

Please provide the solution on a new sheet!
The following Kripke structure is given including the bit vector encoding of the states:

3.1. Describe the characteristic function of each state (using variables $x_{1}$ and $x_{2}$ )!

$$
C_{00}=\neg x_{1} \wedge \neg x_{2} ; C_{01}=\neg x_{1} \wedge x_{2} ; C_{10}=x_{1} \wedge \neg x_{2} ;
$$

3.2. Describe the characteristic function of the set of states labeled with $p$ !

$$
C_{\{00,01\}}=\left(\neg x_{1} \wedge \neg x_{2}\right) \vee\left(\neg x_{1} \wedge x_{2}\right)
$$

3.3. Describe the characteristic function of the transition relation (containing all transitions of the Kripke structure)!

$$
\begin{aligned}
C_{R}= & \left(\neg x_{1} \wedge \neg x_{2} \wedge \neg x_{1}^{\prime} \wedge x_{2}^{\prime}\right) \vee \\
& \left(\neg x_{1} \wedge \neg x_{2} \wedge x_{1}^{\prime} \wedge \neg x_{2}^{\prime}\right) \vee \\
& \left(\neg x_{1} \wedge x_{2} \wedge x_{1}^{\prime} \wedge \neg x_{2}^{\prime}\right) \vee \\
& \left(x_{1} \wedge \neg x_{2} \wedge \neg x_{1}^{\prime} \wedge x_{2}^{\prime}\right)
\end{aligned}
$$

3.4. Run the semantics-based model checking procedure based on the iterative labeling algorithm to check if the CTL expression $\mathbf{A}((\mathbf{E X} p) \mathbf{U} \neg q)$ holds for the initial state! For every step of the iteration, give the labeling expression and enumerate the labeled states!

1 point

1 point

2 points

4 points

1. iteration: (labeling with $\neg q$ )

00
01
2. iteration: (labeling with $\mathbf{E X} p$ )

00
10
3. iteration: (labeling with $\mathbf{A}((\mathbf{E X} p) \mathbf{U} \neg q)$ )

01 (because of $\neg q$ )
10 (because of $\mathbf{E X} p$ and every successor is labeled with $\mathbf{A}((\mathbf{E X} p) \mathbf{U} \neg q)$ )
00 (because of $\mathbf{E X} p$ and now every successor is labeled with $\mathbf{A}((\mathbf{E X} p) \mathbf{U} \neg q)$ )

## 4. LTL requirement formalization (8 points)

The behavior of a beer in a dormitory room is modeled with the Kripke structure on the right (the initial state is A). The behavior of Steve (a student in the dormitory) is defined by the following rules (the rules are in the form: <condition> -> <state transition>):

```
var steve: {sleeping, sober, drunk}
initialization:
    steve := sleeping
transition rules:
    steve = sober && beer = full -> steve := drunk
    steve = sober && beer = empty -> steve := sleeping
    steve = sleeping -> steve := sober
    steve = drunk -> steve := sleeping
```

Furthermore, we know that during the time Steve gets drunk, he drinks all the beer.
4.1. First, give the Kripke structure representing Steve. Note that in some cases the behavior of Steve depends on the state of the beer. In such cases assume that the beer can be in any state. Use the state labels $\{$ sleeping, sober, drunk\} to describe Steve! Then, give the Kripke structure representing the whole system (i.e., Steve and the beer)! In this case, the states will be pairs.
4.2. Use LTL expressions to formalize the following requirements, which must apply to the behavior of the system in every case! Use the labels introduced in the previous subtask! Note that the requirements may or may not hold for the actual system.

\{drunk\}
 It is universally true that Steve will eventually be sober.

## GF sober

4.2-2. It is universally true that when Steve is drunk, he will be sleeping at the next step.

$$
\mathbf{G}(d r u n k \Rightarrow \mathbf{X} \text { sleeping })
$$

4.2-3. It is universally true that if Steve is sober, he will not get drunk until the beer is empty.
$\mathbf{G}$ (sober $\Rightarrow(\neg$ drunk $\mathbf{U}$ empty) $)$

## 5. Statecharts (8 points)

Consider the following statechart, in which for all states $s_{k}$ there is also an entry action $s_{k}$ entry and an exit action $s_{k}$ exit that is not displayed in the figure. The expressions on the arrows (transitions) have the following form: transition_name: trigger [guard] / action. Guards are given as expressions, actions are given as letters (such as $n$ ) or by assignments (such as $g:=$ true).

The current state of the statechart is the following state configuration: ( $s 0, \mathrm{~s} 3, \mathrm{~s} 4, \mathrm{~s} 6$ ) and the value of the logical variable $g$ is true. The incoming event is $z$.
5.1. Which transitions are enabled?

1 point
t3, t5, t7, t8
5.2. Which enabled transitions are in conflict?
( $\mathrm{t} 3, \mathrm{t} 7$ ), ( $\mathrm{t} 3, \mathrm{t} 8$ ), ( $\mathrm{t} 5, \mathrm{t} 7$ ), ( $\mathrm{t} 5, \mathrm{t} 8$ ), ( $\mathrm{t} 7, \mathrm{t} 8$ )
5.3. What is the set of fireable transitions after resolving the conflicts? If there are multiple sets of fireable transitions, give all sets!
\{t3, t5\}
5.4. What is (are) the next stable state configuration(s)? If there are more than one possible stable state configurations, give all of them! Give the actions and their order during firing the transitions! Do not forget to include the entry and exit actions!

2 points

Next stable state configuration: $\{\mathrm{s} 0, \mathrm{~s} 3, \mathrm{~s} 5, \mathrm{~s} 7\}$
Actions: Any interleaving of (s4.exit, n, s5.entry) and (s6.exit, q, s7.exit), e.g. (s4.exit, n, s5.entry, s6.exit, q, s7.exit)
5.5. Decide whether the following statements are true or false! Explain the answer (on a separate sheet)! Reachability is considered from the initial configuration with arbitrary incoming event(s).
a) A configuration can be reached where $t_{8}$ is fireable.

False, because in every state, there will be a higher-priority enabled transition ( $\mathrm{t} 1, \mathrm{t} 2$ or t 7 ).
b) The configuration ( $\mathrm{s} 0, \mathrm{~s} 3, \mathrm{~s} 4, \mathrm{~s} 7$ ) is reachable.

False, because the transitions in concurrent regions must fire together.
c) A configuration can be reached where the next configuration is not deterministic (there are more possibilities) even if the incoming event and the guard is known.
False, because there are no states with multiple outgoing transitions with the same trigger and overlapping guards.
