A style of software architecture for distributed systems

## Who/Where/When?

# REST

## What does it stand for?:

Representational **State Transfer**

## What Is it?

A style of software architecture for distributed systems

## Who/Where/When?

Came about in 2000 doctoral dissertation of Roy Fielding – but it's been used for much longer

# Core principles

- Client-server
- Stateless
- Cacheable
- Layered
- Code on demand (optional)
- Uniform interfaces
  - URIs
  - Metadata
  - Self-descriptive

# REST – Core Principles

# REST – Core Principles

Resources: Data, files, methods

Where:  
URL based

How: HTTP

What: Up  
to you

# REST – Where/How: Simple Example

# REST – Where/How: Simple Example

## Premise:

Data in a table could be a resource we want to read

Database server called *bbddb01*

Database called *northwind*

Table called *users*

- <http://bbddb01/northwind/users>

# What, What, What?

- What type of content you return is up to you.
- Compare to SOAP where you must return XML.
- Most common are XML or JSON. You could return complex types like a picture.

# REST – Is it used?

# REST – Is it used?

- Web sites are RESTful

# REST – Is it used?

- Web sites are RESTful
- RSS is RESTful

# REST – Is it used?

- Web sites are RESTful
- RSS is RESTful
- Twitter, Flickr and Amazon expose data using REST

# REST – Is it used?

- Web sites are RESTful
- RSS is RESTful
- Twitter, Flickr and Amazon expose data using REST

# REST – Is it used?

- Web sites are RESTful
- RSS is RESTful
- Twitter, Flickr and Amazon expose data using REST
- Some things are “accidentally RESTful” in that they offer limited support.

# Real Life: Flickr API

- Resource: Photos
- Where:
  - ❖ [http://farm{farm-id}.static.flickr.com/{server-id}/{id}\\_{secret}.jpg](http://farm{farm-id}.static.flickr.com/{server-id}/{id}_{secret}.jpg)
  - ❖ [http://farm{farm-id}.static.flickr.com/{server-id}/{id}\\_{secret}\\_{mstb}.jpg](http://farm{farm-id}.static.flickr.com/{server-id}/{id}_{secret}_{mstb}.jpg)
  - ❖ [http://farm{farm-id}.static.flickr.com/{server-id}/{id}\\_{o-secret}\\_o.\(jpg|gif|png\)](http://farm{farm-id}.static.flickr.com/{server-id}/{id}_{o-secret}_o.(jpg|gif|png))
- What: JPEG, GIF or PNG (defined in the URL)
- [http://farm1.static.flickr.com/2/1418878\\_1e92283336\\_m.jpg](http://farm1.static.flickr.com/2/1418878_1e92283336_m.jpg)

# REST – Methods

HTTP Methods are a key corner stone in REST.

They define the action to be taken with a URL.

Proper RESTful services expose all four – “accidental” expose less.

Nothing stopping you doing some Mix & Match

❖ Some URL's offering all of them and others a limited set

**What are the four methods and what should they do?**

# REST – Methods

HTTP Methods are a key corner stone in REST.

They define the action to be taken with a URL.

Proper RESTful services expose all four – “accidental” expose less.

Nothing stopping you doing some Mix & Match

❖ Some URL's offering all of them and others a limited set

**What are the four methods and what should they do?**

REST	CRUD (Create, Read, Update, Delete)
<i>POST</i>	<i>Create</i>
<i>GET</i>	<i>Read</i>
<i>PUT</i>	<i>Update or Create</i>
<i>DELETE</i>	<i>Delete</i>

# REST – Methods Example

# REST – Methods Example

**`http://bbddb01/northwind/users[firstname="rob%"]`**

# REST – Methods Example

**http://bbddb01/northwind/users[firstname="rob%"]**

**+ POST = Error**

**+ GET = Returns everyone who begins with rob**

**+ PUT = Error**

**+ DELETE = Deletes everyone who begins with rob**

# REST – Methods Example

**`http://bbddb01/northwind/users[firstname="rob%"]`**

**+ POST = Error**

**+ GET = Returns everyone who begins with rob**

**+ PUT = Error**

**+ DELETE = Deletes everyone who begins with rob**

**`http://bbddb01/northwind/users`**

**& we add some input data**

# REST – Methods Example

**http://bbddb01/northwind/users[firstname="rob%"]**

+ POST = Error

+ GET = Returns everyone who begins with rob

+ PUT = Error

+ DELETE = Deletes everyone who begins with rob

**http://bbddb01/northwind/users**

**& we add some input data**

+ POST = Creates a new user

+ GET = Returns everyone who meets criteria

+ PUT = Creates/Updates a user (based on data)

+ DELETE = Deletes everyone who meets criteria

# REST – Methods Example

**`http://bbddb01/northwind/users[firstname="rob%"]`**

+ POST = Error

+ PUT = Error

# REST – Methods Example

**`http://bbddb01/northwind/users[firstname="rob%"]`**

+ POST = Error

+ PUT = Error

**What would the error be?**

**HTTP 400 or 500 errors are normally used to indicate problems – same as websites**

# REST – Commands

You can associate commands with a resource.

Commands can replace the need for using HTTP methods and can provide a more familiar way of dealing with data.

## Example:

```
userResource = new Resource('http://example.com/users/001')  
userResource.delete()
```

## Comparison: REST vs. SOAP

Comparing apples and oranges

# REST vs. SOAP – pt I: Technology

REST	SOAP
<b><u>A STYLE</u></b>	<i>A Standard</i>
<i>Proper REST: Transport must be HTTP/HTTPS</i>	<i>Normally transport is HTTP/HTTPS but can be something else</i>
<i>Response data is normally transmitted as XML, can be something else.</i> ❖ <i>On average the lighter of the two as does not have SOAP header overhead</i>	<i>Response data is transmitted as XML</i>
<i>Request is transmitted as URI</i> ❖ <i>Exceptionally light compared to web services</i> ❖ <i>Limit on how long it can be</i> ❖ <i>Can use input fields</i>	<i>Request is transmitted as XML</i>
<i>Analysis of method and URI indicate intent</i>	<i>Must analyse message payload to understand intent</i>
...	<i>WS* initiatives to improve problems like compression or security</i>

# REST vs. SOAP – pt II: Languages

REST	SOAP
<i>Easy to be called from JavaScript</i>	<i>JavaScript can call SOAP but it is hard, and not very elegant.</i>
<i>If JSON is returned it is very powerful (keep this in mind)</i>	<i>JavaScript parsing XML is slow and the methods differ from browser to browser.</i>
<i>C# (Visual Studio) parsing of REST means using <code>HttpRequest</code> and parsing the results (string/xml) or normal service consumption (.NET 3.5 SP 1 and later).</i>	<i>C# (Visual Studio) makes consuming SOAP very easy and provides nice object models to work with.</i>
<i>C# version 4 should make this easier thanks to new dynamic methods.</i>	...
<i>There are 3 with C# so that may make it easier.</i>	...

# REST vs. SOAP – pt III: Tools

REST	SOAP
<i>Basic support for REST in BizTalk</i>	<i>BizTalk and SOAP are made to be together.</i>
<i>WCF can consume REST.</i>	<i>WCF can consume SOAP.</i>
<i>WCF can serve REST with a bit of tweaking.</i>	<i>WCF can server SOAP.</i>
<i>The new routing feature in ASP.NET 3.5 SP1 makes building a RESTful service easy.</i>	<i>...</i>

# FAQ about Security?

- Are RESTful services secure?

# FAQ about Security?

- Are RESTful services secure?
  - It's a style, not a technology so that depends on how you implement it.

# FAQ about Security?

- Are RESTful services secure?
  - It's a style, not a technology so that depends on how you implement it.
- Are you open to SQL injection attacks?

# FAQ about Security?

- Are RESTful services secure?
  - It's a style, not a technology so that depends on how you implement it.
- Are you open to SQL injection attacks?
  - When you look at *http://bbddb01/northwind/users[firstname="rob %"]*, you may think so but you shouldn't be. Because:
    - 1) The parameter shouldn't be SQL
    - 2) If it is SQL, why are you not filtering it?
    - 3) Remember the old rule: Do not trust user input

# FAQ about Security?

- How can I do authentication?

# FAQ about Security?

- **How can I do authentication?**

- It's built on HTTP, so everything you have for authentication in HTTP is available
- PLUS
- You could encode your authentication requirements into the input fields

# JSON

# JSON – What is it?

# JSON – What is it?

- *“JSON (JavaScript Object Notation) is a **lightweight data-interchange format**. It is easy for humans to read and write. It is easy for machines to parse and generate” – JSON.org*

# JSON – What is it?

- *“JSON (JavaScript Object Notation) is a **lightweight data-interchange format**. It is easy for humans to read and write. It is easy for machines to parse and generate” – JSON.org*
- Importantly: JSON is a subset of JavaScript

# JSON – What does it look like?

```
{  
  "firstName": "John",  
  "lastName": "Smith",  
  "address": {  
    "streetAddress": "21 2nd Street",  
    "city": "New York",  
    "state": "NY",  
    "postalCode": 10021  
  },  
  "phoneNumbers": [  
    "212 555-1234",  
    "646 555-4567"  
  ]  
}
```

# JSON – What does it look like?

```
{  
  "firstName": "John",  
  "lastName": "Smith",  
  "address": {  
    "streetAddress": "21 2nd Street",  
    "city": "New York",  
    "state": "NY",  
    "postalCode": 10021  
  },  
  "phoneNumbers": [  
    "212 555-1234",  
    "646 555-4567"  
  ]  
}
```

Name/Value Pairs

Child properties

String Array

Number data type

# JSON vs. XML

JSON	XML
<b>Data Structure</b>	<b>Data Structure</b>
<b>No validation system</b>	<b>XSD</b>
<b>No namespaces</b>	<b>Has namespaces (can use multiples)</b>
<b>Parsing is just an eval</b> •Fast	<b>Parsing requires XML document parsing</b> <b>using things like XPath</b>
<b>In JavaScript you can work with objects – runtime evaluation of types</b>	<b>In JavaScript you can work with strings – may require additional parsing</b>
<b>Security: Eval() means that if the source is not trusted anything could be put into it.</b>	<b>Security: XML is text/parsing – not code execution.</b>

# JSON vs. XML which to use?

- Scenario 1: You have a website (say Twitter.com) and you want to expose a public API to build apps.

Issue	JSON	XML
<i>The public will be parsing data in. You must make it secure.</i>	<i>Run checks against the data in the object to make sure it's secure. You are working on objects so you must also check for potential code access issues.</i>	<i>Run checks against the data to make sure it's secure.</i>
<i>Data must be in a specific format.</i>	<i>Build something that parses the objects.</i>	<i>XML Schema</i>

# JSON vs. XML which to use?

- Scenario 2: You have a website (say gmail.com) and your front end needs to show entries from a mailbox, but needs to be dynamic and so you will use a lot of JavaScript.

Issue	JSON	XML
<i>Your in house developers know objects and would like to use them.</i>	<i>JSON is JavaScript objects.</i>	<i>Write JavaScript to parse the XML to objects.</i>
<i>The site is secure but you worry about people</i>	<i>You page has JavaScript in it and (maybe) code which communicates with a private</i>	<i>You page has JavaScript in it and (maybe) code which communicates with a</i>

# JSON vs. XML

# JSON vs. XML

- **Which of them should you use?**
  - Use Both – They both have strengths and weaknesses and you need to identify when one is stronger than the other.

# Restful Web Services Frameworks and APIs

- **JAX-RS - The Java API for RESTful Web Services**
- **uses annotations to make plain old Java objects (POJOs) and resources available through HTTP**
- **Sun Reference Project: Jersey**
- **Other Vendors: CXF (Apache), RESTEasy(JBoss) and Restlet**
  
- **JAX-RS tutorial:**  
<http://docs.oracle.com/javaee/6/tutorial/doc/gilik.html>

**Source: <http://www.slideshare.net/kverbert/using-java-to-implement-rest-web-services-jaxrs>**

- **Templated mapping and subresources**  
`@Path`
- **MIME handling**  
`@Provides`, `@Consumes`
- **HTTP methods**  
`@GET`, `@POST`, `@UPDATE`, `@DELETE`, `@HEAD`,  
`@OPTIONS`, `@HttpMethod`
- **Caching**  
`evaluatePreconditions`

# Example

```
package com.sun.jersey.samples.helloworld.resources;
import javax.ws.rs.GET;
import javax.ws.rs.Produces;
import javax.ws.rs.Path;

// The Java class will be hosted at the URI path "/helloworld"
@Path("/helloworld")
public class HelloWorldResource {

    // The Java method will process HTTP GET requests
    @GET
    // The Java method will produce content identified by the MIME Media
    // type "text/plain"
    @Produces("text/plain")
    public String getClicheMessage() {
        // Return some cliched textual content
        return "Hello World";
    }
}
```

# @Path Annotation and URI Path Templates

## @Path annotation

- identifies the URI path template to which the resource responds
- is specified at the class or method level of a resource

URI path templates are URIs with variables embedded within the URI syntax

- these variables are substituted at runtime
- variables are denoted by braces ( { and } )

`@Path("/users/{username}")`

- example request

<http://example.com/users/Galileo>

# @PathParam annotation

To obtain the value of the user name, the `@PathParam` annotation may be used on the method parameter of a request method

```
@Path("/users/{username}")
```

```
public class UserResource {
```

```
    @GET
```

```
    @Produces("text/xml")
```

```
    public String getUser(@PathParam("username") String userName) {
```

```
        ...
```

```
    }
```

```
}
```

# Examples of URI Path Templates

URI Path Template	URI After Substitution
<code>http://example.com/{name1}/{name2}/</code>	<code>http://example.com/james/gatz/</code>
<code>http://example.com/{question}/ {question}/{question}/</code>	<code>http://example.com/why/why/why/</code>
<code>http://example.com/maps/{location}</code>	<code>http://example.com/maps/Main %20Street</code>

# @Produces Annotation

**@Produces** annotation is used to specify the **MIME** media types or representations a resource can produce and send back to the client

- applied at the class level: default for all methods
- applied at the method level overrides any **@Produces** annotations applied at the class level

# @Produces annotation

```
@Path("/myResource")
@Produces("text/plain")
public class SomeResource {
    @GET
    public String doGetAsPlainText() {
        ...
    }

    @GET
    @Produces("text/html")
    public String doGetAsHtml() {
        ...
    }
}
```

# @Consumes Annotation

**@Consumes** annotation is used to specify which MIME media types of representations a resource can accept

```
@POST
```

```
@Consumes("text/plain")
```

```
public void postClickedMessage(String message) {
```

```
    // Store the message
```

```
}
```

# Using Java to implement SOAP web Services: JAX-WS

Web Technology  
2II25

Dr. Katrien Verbert

Dr. ir. Natasha Stash

Dr. George Fletcher

**TU** / **e**

Technische Universiteit  
**Eindhoven**  
University of Technology

**Where innovation starts**

# JAX-WS 2.0

- Part of Java EE
- New in Java SE 6
- API stack for web services.
- New API's:
  - JAX-WS, SAAJ, Web Service metadata
- New packages:
  - javax.xml.ws, javax.xml.soap, javax.jws

# Java Web Services Basics

- **Remote machine or server**
  - The computer on which a web service resides
- **A client application that accesses a web service sends a method call over a network to the remote machine, which processes the call and returns a response over the network to the application**
- **In Java, a web service is implemented as a class that resides on a server**
- **Publishing a web service**
  - Making a web service available to receive client requests
- **Consuming a web service**
  - Using a web service from a client application

# Communication between JAX-WS Web Service and Client

# Java Web Services Basics

# Writing a webservice

```
package loanservice;
```

```
import javax.jws.WebService;  
import javax.jws.WebMethod;  
import javax.xml.ws.Endpoint;
```

```
@WebService
```

```
public class LoanApprover {
```

```
    @WebMethod
```

```
    public boolean approve(String name) {  
        return name.equals("Mike");
```

```
    }
```

```
}
```

# Annotations

Annotations are a new feature of JDK 1.5 and later.

- Essentially they are markers in the Java source code
- That can be used by external tools to generate code

Format looks like

```
@ThisIsAnAnnotation(foo="bar")
```

Annotations can occur only in specific places in the code

- before a class definition,
- before a method declaration, ...

# Requirements of a JAX-WS Endpoint

# Requirements of a JAX-WS Endpoint

- The implementing class must be annotated with the `@WebService` or `@WebServiceProvider` annotation

# Requirements of a JAX-WS Endpoint

- The implementing class must be annotated with the `@WebService` or `@WebServiceProvider` annotation
- The business methods of the implementing class must be public.

# Requirements of a JAX-WS Endpoint

- The implementing class must be annotated with the **@WebService** or **@WebServiceProvider** annotation
- The business methods of the implementing class must be public.
- The business methods must not be declared static or final.

# Requirements of a JAX-WS Endpoint

- The implementing class must be annotated with the **@WebService** or **@WebServiceProvider** annotation
- The business methods of the implementing class must be public.
- The business methods must not be declared static or final.
- Business methods that are exposed to web service clients must be annotated with **@WebMethod**.

# Requirements of a JAX-WS Endpoint

- The implementing class must be annotated with the **@WebService** or **@WebServiceProvider** annotation
- The business methods of the implementing class must be public.
- The business methods must not be declared static or final.
- Business methods that are exposed to web service clients must be annotated with **@WebMethod**.
- Business methods that are exposed to web service clients must have JAXB-compatible parameters and return types.
  - See the list of JAXB default data type bindings at
  - <http://docs.oracle.com/javaee/5/tutorial/doc/bnazq.html#bnazs>.

# @WebService annotation

- Indicates that a class represents a web service
- Optional element **name**
  - specifies the name of the proxy class that will be generated for the client
- Optional element **serviceName**
  - specifies the name of the class to obtain a proxy object.

# Creating, Publishing, Testing and Describing a Web Service

## Calculator web service

- Provides method that takes two integers
- Can determine their sum

# CalculatorWS example

```
import javax.jws.WebService;  
import javax.jws.WebMethod;  
import javax.jws.WebParam;
```

```
@WebService(serviceName = "CalculatorWS")
```

```
public class CalculatorWS {
```

```
    @WebMethod
```

```
    public int add (@WebParam (name= "value1") int value1,
```

```
        @WebParam( name="value2" ) int value2){
```

```
        return value1 + value2;
```

```
    }
```

```
}
```

Declare that method add is a WebMethod

Specify parameter names

# Coding the Service Endpoint Implementation Class

- **@WebService** annotation at the beginning of each new web service class you create
- **@WebMethod** annotation at the beginning of each method that is exposed as a WSDL operation
  - Methods that are tagged with the **@WebMethod** annotation can be called remotely
  - Methods that are not tagged with **@WebMethod** are not accessible to clients that consume the web service
- **@WebParam** annotation is used here to control the name of a parameter in the WSDL
  - Without this annotation the parameter name = arg0

- **@WebMethod** annotation
  - Optional `operationName` element to specify the method name that is exposed to the web service's client
- Parameters of web methods are annotated with the **@WebParam** annotation
  - Optional `name` element indicates the parameter name that is exposed to the web service's clients

## Java IDEs

- Netbeans

- Eclipse
  - download: <http://www.eclipse.org/>
  - tutorial: <http://rantincsharp.wordpress.com/2008/10/14/a-simple-soap-web-service-example-in-eclipse-ganymede/>
- IntelliJ IDEA
  - download: <http://www.jetbrains.com/idea/>
  - tutorial: [http://wiki.jetbrains.net/intellij/Web\\_Services\\_with\\_IntelliJ\\_IDEA#JAX\\_WS](http://wiki.jetbrains.net/intellij/Web_Services_with_IntelliJ_IDEA#JAX_WS)

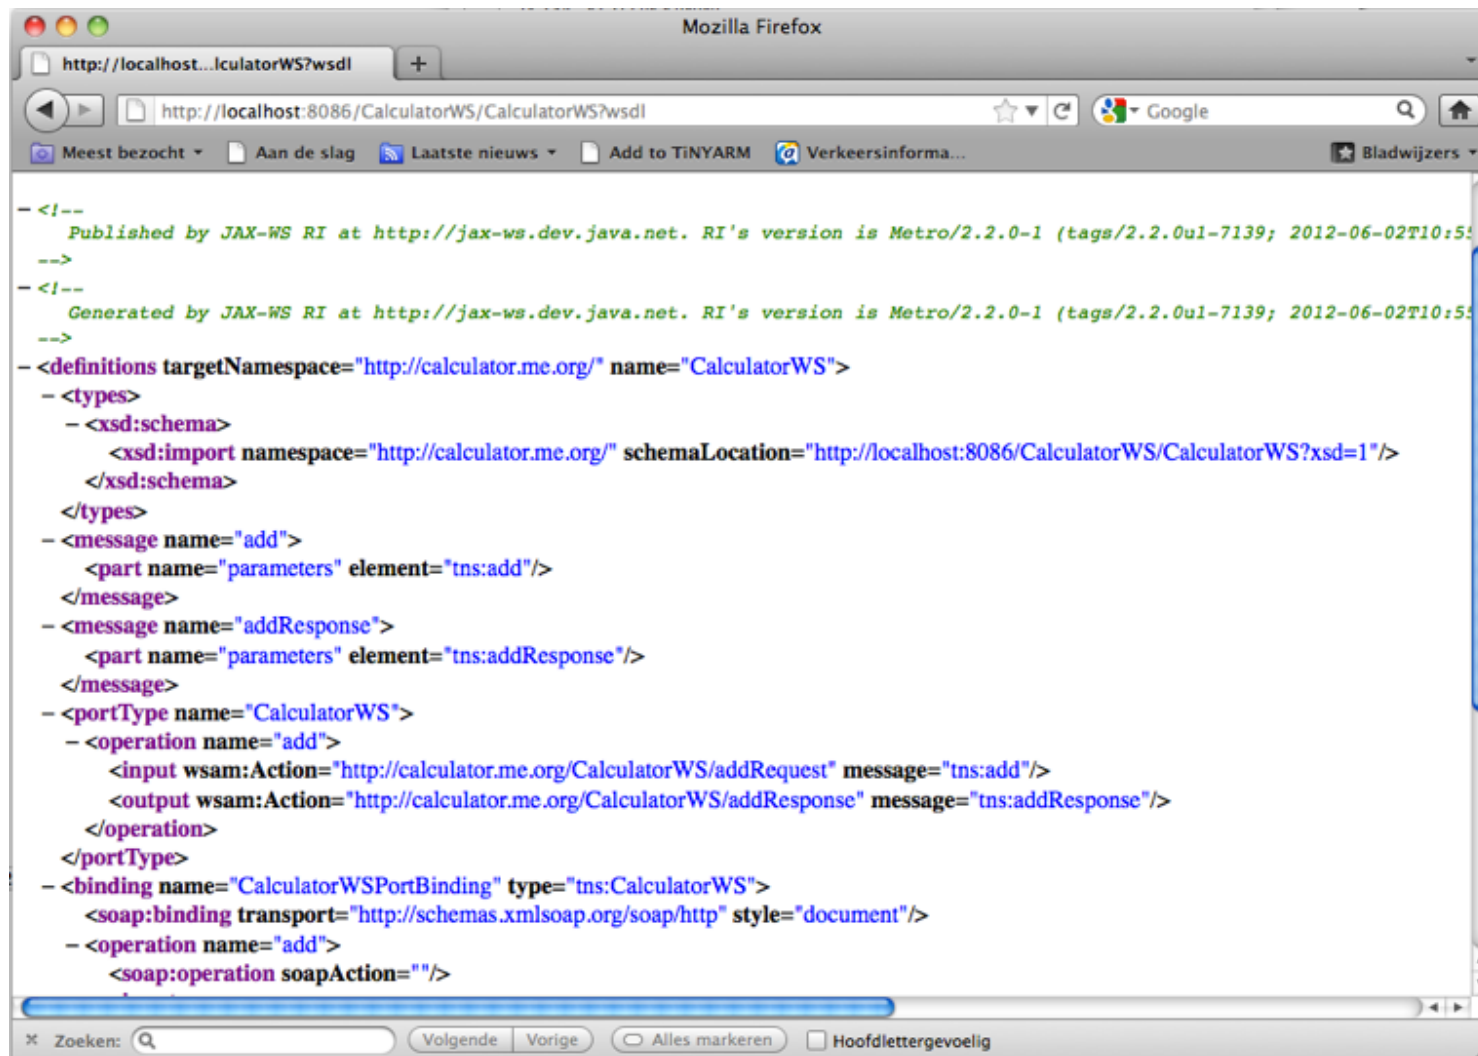

## Using Ant

<http://docs.oracle.com/javase/6/tutorial/doc/bnayn.html>

# Describing a Web Service with the Web Service Description Language (WSDL)

- **To consume a web service**
  - Must know where to find the web service
  - Must be provided with the web service's description
- **Web Service Description Language (WSDL)**
  - Describe web services in a platform-independent manner
  - The server generates a WSDL dynamically for you
  - Client tools parse the WSDL to create the client-side proxy class that accesses the web service
- **To view the WSDL for a web service**
  - Type URL in the browser's address field followed by ?WSDL or
  - Click the WSDL File link in the Sun Java System Application Server's Tester web page

# Example WSDL

```
-<!--
  Published by JAX-WS RI at http://jax-ws.dev.java.net. RI's version is Metro/2.2.0-1 (tags/2.2.0u1-7139; 2012-06-02T10:5
-->
- <!--
  Generated by JAX-WS RI at http://jax-ws.dev.java.net. RI's version is Metro/2.2.0-1 (tags/2.2.0u1-7139; 2012-06-02T10:5
-->
- <definitions targetNamespace="http://calculator.me.org/" name="CalculatorWS">
- <types>
- <xsd:schema>
  <xsd:import namespace="http://calculator.me.org/" schemaLocation="http://localhost:8086/CalculatorWS/CalculatorWS?xsd=1"/>
  </xsd:schema>
</types>
- <message name="add">
  <part name="parameters" element="tns:add"/>
</message>
- <message name="addResponse">
  <part name="parameters" element="tns:addResponse"/>
</message>
- <portType name="CalculatorWS">
- <operation name="add">
  <input wsam:Action="http://calculator.me.org/CalculatorWS/addRequest" message="tns:add"/>
  <output wsam:Action="http://calculator.me.org/CalculatorWS/addResponse" message="tns:addResponse"/>
</operation>
</portType>
- <binding name="CalculatorWSPortBinding" type="tns:CalculatorWS">
  <soap:binding transport="http://schemas.xmlsoap.org/soap/http" style="document"/>
- <operation name="add">
  <soap:operation soapAction=""/>
```

# Creating a Client in Netbeans to Consume a Web Service

- **When you add a web service reference**
  - IDE creates and compiles the client-side artifacts
  - the framework of Java code that supports the client-side proxy class
- **Client calls methods on a proxy object**
  - Proxy uses client-side artifacts to interact with the web service
- **To add a web service reference**
  - Right click the client project name in the Netbeans Projects tab
  - Select New > Web Service Client...
  - Specify the URL of the web service's WSDL in the dialog's WSDL URL field

# Calculator client

```
import calculator.*;

public class CalculatorClient {
    public static void main(String[] args) {
        CalculatorWS_Service service=new CalculatorWS_Service();
        CalculatorWS port= service.getCalculatorWSPort();
        int result = port.add(2, 3);
        System.out.println(result);
    }
}
```

# Parsing XML

## Goal

Read XML files into data structures in programming languages

## Possible strategies

- Parse into generic tree structure (DOM)
- Parse as sequence of events (SAX)
- Automatically parse to language-specific objects (JAXB)

## **JAXB: Java API for XML Bindings**

**Defines an API for automatically representing XML schema as collections of Java classes.**

**Most convenient for application programming**

# Annotations markup

**@XmlAttribute** to designate a field as an attribute

**@XmlRootElement** to designate the document root element.

**@XmlElement** to designate a field as a node element

**@XmlElementWrapper** to specify the element that encloses a repeating series of elements

**Note that you should specify only the getter method as @XmlAttribute or @XmlElement.**

**Jaxb oddly treats both the field and the getter method as independent entities**

# Order example

```
import javax.xml.bind.annotation.*;
```

```
@XmlRootElement
```

```
public class Item {
```

```
    @XmlElement
```

```
    private String itemId;
```

```
    @XmlElement
```

```
    private String itemName;
```

```
    @XmlElement
```

```
    private int quantity;
```

```
    public Item() {
```

```
    }
```

```
}
```

```
}
```

# Order example

```
import javax.xml.bind.annotation.*;  
import java.util.*;
```

```
@XmlElement
```

```
public class Order {
```

```
    @XmlElement
```

```
    private String date;
```

```
    @XmlElement
```

```
    private String customerId;
```

```
    @XmlElement
```

```
    private String customerName;
```

```
    @XmlElement
```

```
    private List<Item> items;
```

```
    public Order() {
```

```
        this.items=new ArrayList<Item>();
```

```
    }
```

```
}
```

# Marshalling

## marshalling

the process of producing an XML document from Java objects

## unmarshalling

the process of producing a content tree from an XML document

**JAXB only allows you to unmarshal valid XML documents**

**JAXB only allows you to marshal valid content trees into XML**

# Marshalling example

```
public String toXmlString(){
    try{
        JAXBContext context=JAXBContext.newInstance(Order.class);
        Marshaller m = context.createMarshaller();
        m.setProperty(Marshaller.JAXB_FORMATTED_OUTPUT, Boolean.TRUE);
        ByteArrayOutputStream b=new ByteArrayOutputStream();
        m.marshal(this,b);
        return b.toString();
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
}
```

# Unmarshalling example

```
public Order fromXmlString(String s){
    try{
        JAXBContext jaxbContext = JAXBContext.newInstance(Order.class);
        Unmarshaller jaxbUnmarshaller = jaxbContext.createUnmarshaller()
        Order order = (Order) jaxbUnmarshaller.unmarshal(new StreamSource( new
            StringReader(s)));
        return order;
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
}
```

# Test transformation

```
public static void main(String args[]){  
    Order o=new Order("1 March 2013", "123", "Katrien");  
    o.getItems().add(new Item("1", "iPhone 5", 2));  
    o.getItems().add(new Item("2", "Nokia Lumia 800", 2));  
    System.out.println(o.toXmlString());  
  
}
```

# Output

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<order>
  <customerId>123</customerId>
  <customerName>Katrien Verbert</customerName>
  <date>12 February 2013</date>
  <items>
    <itemId>id1</itemId>
    <itemName>Iphone 5</itemName>
    <quantity>2</quantity>
  </items>
  <items>
    <itemId>id2</itemId>
    <itemName>Nokia Lumia 800</itemName>
    <quantity>1</quantity>
  </items>
</order>
```

# Developing Cloud Applications with Eclipse Gyrex

Gunnar Wagenknecht, @guw

<http://www.eclipsecon.org/europe2012/sessions/developing-cloud-applications-eclipse-gyrex>

# Modern Server Applications

- **High traffic**
- **Different frontend technologies and devices**
- **Modular** in development and deployment
- **Easy** to setup and run
- **Open** for new technologies
  - e.g. persistence

Million transactions  
per hour

# Eclipse Gyrex

A lightweight **application stack** for building server applications using **EclipseRT** technologies.

GYREX

# EclipseRT (RT = Runtime)

“EclipseRT is the collection of OSGi-based runtimes and frameworks built by the Eclipse open source projects. “

Containers, Middleware, EnterpriseFrameworks

OSGI

GYREX

eclipseRT

# Equinox

- **OSGi** reference implementation
- Foundation of EclipseRT
- **C**omponent **O**riented **D**evelopment and **A**ssembly

*Create*

*Extend*

*Assemble*

# Jetty

- Asynchronous HTTP Server and Client
- Standards based Servlet Container
- Web Sockets server
- OSGi, JNDI, JMX, JASPI, AJP support
  
- Small foot print
- Excellent scalability
  
- Runs in
  - Apache Hadoop
  - Google AppEngine

The logo for Jetty, featuring the word "jetty" in a bold, italicized, red font with a black outline, followed by "://".

# EclipseLink

Comprehensive Java persistence solution  
addressing relational, XML, and database web services.

XML Data

Legacy Systems

# Gyrex

- built-in **clustering**
- built-in **web-based administration UI**
- built-in **multi tenancy**
- enhancements for **professional maintenance**
  - centralized logging UI
  - centralized provisioning UI

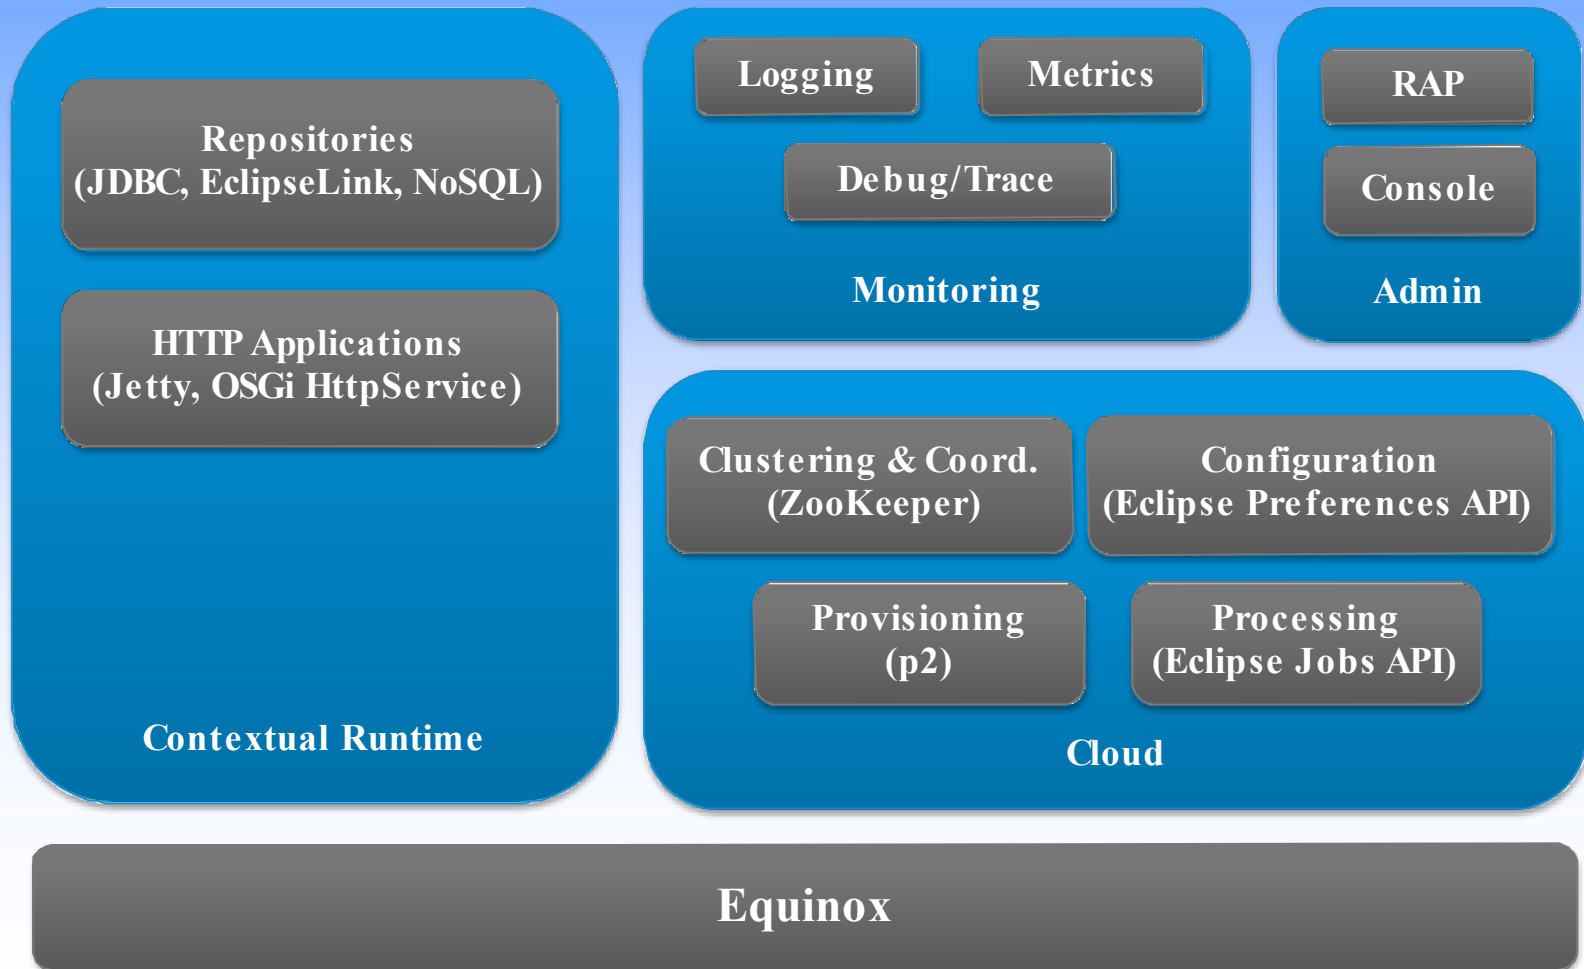

GYREX

# Gyrex Features

- lightweight **application stack**
- fast **100% OSGi** runtime
- central **cluster** configuration through Apache ZooKeeper
- cluster aware **job scheduling**
- **automated deployment** through p2
- support for cluster **node roles**, e.g. “job worker node” and “api node”

# Gyrex Components

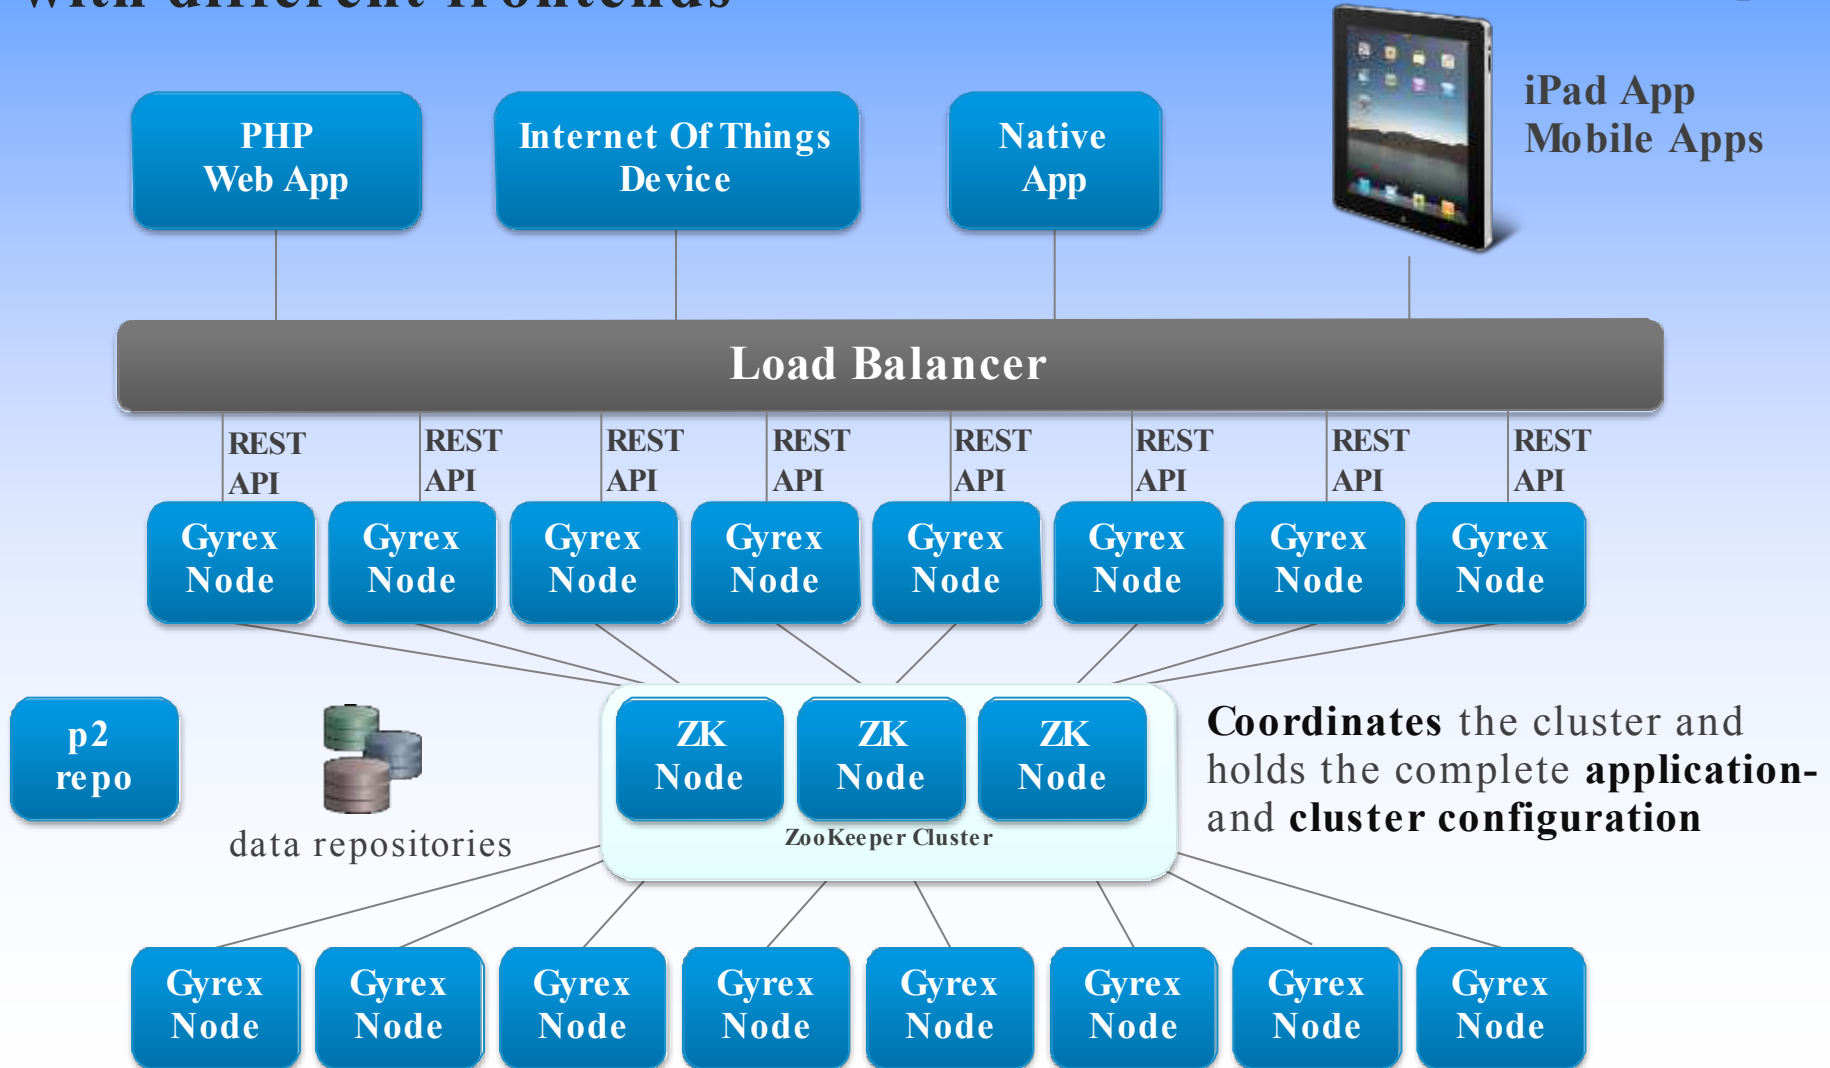

# Gyrex Infrastructure Setup

For a high traffic application with different frontends
