

# Model checking CTL: Symbolic technique

Istvan Majzik  
majzik@mit.bme.hu

**Budapest University of Technology and Economics**  
**Dept. of Measurement and Information Systems**

# Formal verification of TL properties

# Recap: Techniques for model checking

- HML model checking: Tableau-based

- LTL model checking: Based on automata-theory

- CTL model checking: Iterative labeling

# Problems

- The state space (e.g., Kripke structure) to check can be **huge**
  - **Concurrent systems** exhibit a large state space: Combinatorial explosion in the number of possible **orderings of independent state transitions**

- How can we analyze large state spaces?
  - Promise: CTL model checking:  $10^{20}$ , sometimes even  $10^{100}$  states
  - What kind of technique can deliver this promise?

# Example for large state space: Dining philosophers

- Concurrent system with non-trivial behavior
  - May have deadlock, livelock
- State space grows fast

#Philosophers	#States
16	$4,7 \cdot 10^{10}$
28	$4,8 \cdot 10^{18}$
...	...
200	$> 10^{40}$
1000	$> 10^{200}$
...	...

$$2^{64} = 1,8 \cdot 10^{19}$$

With smart (but not task-specific) state space representation:  
~100 000 philosophers, i.e.  
 $10^{62\ 900}$  states can be checked!

# Techniques for handling large state space

## ■ CTL model checking: **Symbolic technique**

State enumeration technique	Symbolic technique
Sets of labeled states	Characteristic functions (Boolean functions) with ROBDD representation
Operations on sets of states	Efficient operations on ROBDDs

## ■ Model checking of invariants: **Bounded model checking**

- Model checking to a given depth in the state space:  
Searching for counterexamples with bounded length
  - A detected counterexample is always valid
  - Non-existing counterexample does not imply correctness
- Background: Searching satisfying valuations for Boolean formulas with **SAT techniques**

# Symbolic model checking

# Recap: Model checking with set operations

- We need sets of states that have proper successor states
  - $E(p \cup q)$ : “At least one successor state is labeled ...”
  - $A(p \cup q)$ : “All successor states are labeled ...”
- Notation: If the set of states labeled with  $p$  is  $Z$  then
  - $\text{pre}_E(Z) = \{s \in S \mid \text{there exists } s', \text{ such that } (s, s') \in R \text{ and } s' \in Z\}$   
i.e., at least one successor is in  $Z$  (already labeled)
  - $\text{pre}_A(Z) = \{s \in S \mid \text{for all } s' \text{ where } (s, s') \in R: s' \in Z\}$   
i.e., all successors are in  $Z$  (already labeled)
- Example: Iterative labeling with  $E(P \cup Q)$ 
  - Initial set:  $X_0 = \{s \mid Q \in L(s)\}$
  - Next iteration:  $X_{i+1} = X_i \cup (\text{pre}_E(X_i) \cap \{s \mid P \in L(s)\})$ 
    - States labeled so far, plus ...
    - ... their predecessor states that ...
    - ... are labeled with  $P$
  - End of iteration: If  $X_{i+1} = X_i$ , the set is not increased

# Main idea

- Representation of **sets of states** and **operations on sets of states** with **Boolean functions**
  - States are not explicitly enumerated
  - Encoding a **state**: with a **bit-vector**
    - To encode each state in  $S$  we need at least  $n = \lceil \log_2 |S| \rceil$  bits, so choose  $n$  such that  $2^n \geq |S|$
  - Encoding a **state / set of states**: Boolean function with  $n$  variables, called **characteristic function**
    - Characteristic function:  $C: \{0,1\}^n \rightarrow \{0,1\}$
    - The characteristic function of a set is 1 (true) for a bit-vector *iff* the state encoded by the bit-vector is in **the given set of states**
  - In model checking, we will perform operations on characteristic functions instead of sets

# Example: Characteristic function of states

Variables:  $x, y$

Characteristic functions of states:

State  $s_1$ :

$$C_{s_1}(x,y) = (\neg x \wedge \neg y)$$

State  $s_2$ :

$$C_{s_2}(x,y) = (\neg x \wedge y)$$

State  $s_3$ :

$$C_{s_3}(x,y) = (x \wedge y)$$

Characteristic function for a set of states:

Set of states  $\{s_1, s_2\}$ :

$$C_{\{s_1, s_2\}} = C_{s_1} \vee C_{s_2} = (\neg x \wedge \neg y) \vee (\neg x \wedge y)$$

# Construction of characteristic functions

## ■ For a state $s$ : $C_s(x_1, x_2, \dots, x_n)$

Let the encoding of  $s$  be the bit-vector  $(u_1, u_2, \dots, u_n)$ , where  $u_i \in \{0,1\}$

Goal:  $C_s(x_1, x_2, \dots, x_n)$  should return be **true** only for  $(u_1, u_2, \dots, u_n)$

Construction of  $C_s(x_1, x_2, \dots, x_n)$ : with operator  $\wedge$  :

- $x_i$  is an operand if  $u_i=1$
- $\neg x_i$  is an operand if  $u_i=0$

Example: for state  $s$  with encoding  $(0,1)$ :  $C_s(x_1, x_2) = \neg x_1 \wedge x_2$

## ■ For a set of states $Y \subseteq S$ : $C_Y(x_1, x_2, \dots, x_n)$

Goal:  $C_Y(x_1, x_2, \dots, x_n)$  should be **true** for  $(u_1, u_2, \dots, u_n)$  iff  $(u_1, u_2, \dots, u_n) \in Y$

Construction of  $C_Y(x_1, x_2, \dots, x_n)$  with operator  $\vee$  :

$$C_Y(x_1, x_2, \dots, x_n) = \bigvee_{s \in Y} C_s(x_1, x_2, \dots, x_n)$$

## ■ For sets of states in general:

$$C_{Y \cup W} = C_Y \vee C_W, \quad C_{Y \cap W} = C_Y \wedge C_W$$

# Construction of characteristic functions (cont'd)

- For state transitions:  $C_r$

- For transition  $r=(s,t)$ , where  $s=(u_1, u_2, \dots, u_n)$  and  $t=(v_1, v_2, \dots, v_n)$  characteristic function in the form  $C_r(x_1, x_2, \dots, x_n, x'_1, x'_2, \dots, x'_n)$ 
  - $2*n$  variables, "primed" variables denote the target state
- Goal:  $C_r$  should be **true** iff  $x_i=u_i$  and  $x'_i=v_i$

Construction of  $C_r$ :

$$C_r = C_s(x_1, x_2, \dots, x_n) \wedge C_t(x'_1, x'_2, \dots, x'_n)$$

# Example: Characteristic functions of transitions

State s1 encoded by (0,0):

$$C_{s1}(x,y) = (\neg x \wedge \neg y)$$

State s2 encoded by (0,1):

$$C_{s2}(x,y) = (\neg x \wedge y)$$

Transition  $(s1, s2) \in R$ , i.e.,  $(0,0) \rightarrow (0,1)$ :

$$C_{(s1,s2)} = (\neg x \wedge \neg y) \wedge (\neg x' \wedge y')$$

Transition relation R:

$$\begin{aligned} R(x,y,x',y') = & (\neg x \wedge \neg y \wedge \neg x' \wedge y') \vee \\ & \vee (\neg x \wedge y \wedge x' \wedge y') \vee \\ & \vee (x \wedge y \wedge \neg x' \wedge y') \vee \\ & \vee (x \wedge y \wedge \neg x' \wedge \neg y') \end{aligned}$$

# Construction of characteristic functions (cont'd)

- Construction of  $\text{pre}_E(Z)$ :  $\text{pre}_E(Z) = \{s \mid \exists t: (s,t) \in R \text{ and } t \in Z\}$ 
  - Representation of  $Z$ : function  $C_Z$
  - Representation of  $R$ : function  $C_R = \bigvee_{r \in R} C_r$
  - $\text{pre}_E(Z)$ : find predecessor states for states of  $Z$

$$C_{\text{pre}_E(Z)} = \exists_{x'_1, x'_2, \dots, x'_n} C_R \wedge C'_Z$$

where  $\exists_x C = C[1/x] \vee C[0/x]$  ("existential abstraction")

- Model checking with set operations:  
reduced to **operations with Boolean functions**
  - Union of sets: Disjunction of functions ( $\vee$ )
  - Intersection of sets: Conjunction of functions ( $\wedge$ )
  - Construction of  $\text{pre}_E(Z)$ : Complex operation (existential abstraction)

# Representation of Boolean functions

Canonic form: **ROBDD**

Reduced, Ordered Binary Decision Diagram

Conceptual construction of ROBDD (overview):

- **Binary decision tree**: Represents binary decisions given by the valuation of function variables
- **BDD**: Identical subtrees are merged
- **OBDD**: Evaluation of variables in the same order on every branch
- **ROBDD**: Reduction of redundant nodes
  - If both two outcomes (branches) lead to the same node

# ROBDD in more detail

# Types of decision trees

Decision tree for Boolean functions:

**Substitution** (valuation) of a **variable** is a decision

- Example:  $f(x,y)$
- Valuation of all variables results in 1 or 0 in leaf nodes

- We get a **binary decision diagram** (BDD), if we merge all identical subtrees
- We get an **ordered binary decision diagram** (OBDD), if we substitute the variables in the same order during decomposition
- We get a **reduced ordered binary decision diagram** (ROBDD), if we remove redundant nodes (where both decisions lead to the same node)

# Example: From binary decision tree to ROBDD

Binary decision tree

Reduced decision tree

BDD

ROBDD

# ROBDD properties

- Directed, acyclic graph with one root and two leaves
  - Values of the two leaves are **1** and **0** (true and false)
  - Every node is assigned a test variable
- From every node, two edges leave
  - One for the value **0** (notation: dashed arrow)
  - The other for the value **1** (notation: solid arrow)
- On every path, substituted variables are in the same order
- Isomorphic subgraphs are merged
- Nodes from with both edges would point to the same node are reduced

For a given function, two ROBDDs  
with the same variable ordering are **isomorphic**

# Variable ordering for ROBDDs

- Size of ROBDD
  - For some functions it is very compact
  - For others (such as XOR) it may have an exponential size
- The order of variables has a great impact on the ROBDD size
  - A different order may cause an order of magnitude difference
  - Problem of finding an optimal ordering is NP-complete (→heuristics)
- Memory requirements:
  - If the ROBDD is built by combining functions (e.g., representing product automata), **intermediate nodes** may appear which can be reduced later

# Summary: Model checking with ROBDDs

- Implementing model checking:
  - Model checking algorithm: Operations on **sets of states** (labeling)
  - Symbolic technique: Instead of sets, use **Boolean characteristic functions**
  - Efficient implementation: Boolean functions handled as **ROBDDs**
- Benefits
  - ROBDD is a canonical form (equivalence of functions is easy to check)
  - Algorithms can be accelerated (with caching)
  - Reduced storage requirements (depends on variable ordering!)

Dining philosophers:

Number of Philosophers	Size of state space	Number of ROBDD nodes
16	$4,7 \cdot 10^{10}$	747
28	$4,8 \cdot 10^{18}$	1347

Instead of storing  $10^{18}$  states the ROBDD needs ~21kB!

# Supplementary material: Construction and operations on ROBDD

# Boolean functions as binary decision trees

- **Substitution** (valuation) of a **variable** is a decision
- Notation: **if-then-else**

$$x \rightarrow f_1, f_0 = (x \wedge f_1) \vee (\neg x \wedge f_0)$$

- The result is the value of  $f_1$  if  $x$  is true (1)
- The result is the value of  $f_0$  if  $x$  is false (0)
- $x$  is called the **test variable**, checking its value is a **test**
- Shannon decomposition of Boolean functions:

$$\left. \begin{array}{l} f = x \rightarrow f [1/x], f [0/x] \\ \text{let } f_x = f [1/x] ; f_{\underline{x}} = f [0/x] \end{array} \right\} f = x \rightarrow f_x, f_{\underline{x}}$$

- The function is decomposed with if-then-else
- The test variable is substituted, it will not appear in  $f_x, f_{\underline{x}}$
- Repeat until there is a variable left

# Example: Manual construction of an ROBDD

Let

$$f = (a \Leftrightarrow b) \wedge (c \Leftrightarrow d)$$

Variable ordering: a, b, c, d

- $f = a \rightarrow f_a, \underline{f_a}$   
 $f_a = (1 \Leftrightarrow b) \wedge (c \Leftrightarrow d), \underline{f_a} = (0 \Leftrightarrow b) \wedge (c \Leftrightarrow d)$
- $f_a = b \rightarrow f_{a,b}, \underline{f_{a,b}}$   
 $f_{a,b} = (1 \Leftrightarrow 1) \wedge (c \Leftrightarrow d) = (c \Leftrightarrow d)$   
 $\underline{f_{a,b}} = (1 \Leftrightarrow 0) \wedge (c \Leftrightarrow d) = 0$
- $\underline{f_a} = b \rightarrow \underline{f_{a,b}}, \underline{\underline{f_{a,b}}}$   
 $\underline{f_{a,b}} = (0 \Leftrightarrow 1) \wedge (c \Leftrightarrow d) = 0$   
 $\underline{\underline{f_{a,b}}} = (0 \Leftrightarrow 0) \wedge (c \Leftrightarrow d) = (c \Leftrightarrow d)$
- $f_{a,b} = c \rightarrow f_{a,b,c}, \underline{f_{a,b,c}}$   
 $f_{a,b,c} = (1 \Leftrightarrow d), \underline{f_{a,b,c}} = (0 \Leftrightarrow d)$
- $f_{a,b,c} = d \rightarrow f_{a,b,c,d}, \underline{f_{a,b,c,d}}$   
 $f_{a,b,c,d} = (1 \Leftrightarrow 1) = 1,$   
 $\underline{f_{a,b,c,d}} = (1 \Leftrightarrow 0) = 0$
- $\underline{f_{a,b,c}} = d \rightarrow \underline{f_{a,b,c,d}}, \underline{\underline{f_{a,b,c,d}}}$   
 $\underline{f_{a,b,c,d}} = (0 \Leftrightarrow 1) = 0, \underline{\underline{f_{a,b,c,d}}} = (0 \Leftrightarrow 0) = 1$

$f_{a,b}$  and  $\underline{f_{a,b}}$  are isomorphic

# Storing an ROBDD in memory

- Nodes of the ROBDD are identified by Ids (indices)

- The ROBDD is stored in a table

$T: u \rightarrow (i,l,h)$ :

- $u$ : index of node
- $i$ : index of variable ( $x_i, i=1\dots n$ )
- $l$ : index of the node reachable through edge corresponding to 0
- $h$ : index of the node reachable through edge corresponding to 1

low

high

<b>u</b>	<b>i</b>	<b>l</b>	<b>h</b>
<b>0</b>			
<b>1</b>			
<b>2</b>	4	1	0
<b>3</b>	4	0	1
<b>4</b>	3	2	3
<b>5</b>	2	4	0
<b>6</b>	2	0	4
<b>7</b>	1	5	6

# Storing an ROBDD in memory

<b>u</b>	<b>i</b>	<b>l</b>	<b>h</b>
<b>0</b>			
<b>1</b>			
<b>2</b>	4	1	0
<b>3</b>	4	0	1
<b>4</b>	3	2	3
<b>5</b>	2	4	0
<b>6</b>	2	0	4
<b>7</b>	1	5	6

# Handling ROBDDs 1.

## ■ Defined operations:

### ○ $\text{init}(T)$

- Initializes table  $T$
- Only the terminal nodes  $0$  and  $1$  are in the table

### ○ $\text{add}(T,i,l,h):u$

- Creates a new node in  $T$  with the provided parameters
- Returns its index  $u$

### ○ $\text{var}(T,u):i$

- Returns from  $T$  the index  $i$  of the node  $u$

### ○ $\text{low}(T,u):l$ and $\text{high}(T,u):h$

- Returns the index  $l$  (or  $h$ ) of the node reachable from the node with index  $u$  through the edge corresponding to  $0$  (or  $1$ , respectively)

# Handling ROBDDs 2.

- To look up ROBDD nodes, we use another table  
 $H: (i,l,h) \rightarrow u$
- Operations:
  - $\text{init}(H)$ 
    - Initializes an empty  $H$
  - $\text{member}(H,i,l,h):t$ 
    - Checks if the triple  $(i,l,h)$  is in  $H$ ;  $t$  is a Boolean value
  - $\text{lookup}(H,i,l,h):u$ 
    - Looks up the triple  $(i,l,h)$  from table  $H$
    - Returns the index  $u$  of the matching node
  - $\text{insert}(H,i,l,h,u)$ 
    - Inserts a new entry into the table

# Handling ROBDDs 3.

## Creating nodes: $Mk(i,l,h)$

- Where  $i$  is the index of variable,  $l$  and  $h$  are the branches
- If  $l=h$ , i.e. the branches would lead to the same node
  - then we don't need a new node
  - we can return any branches
- If  $H$  already contains a triple  $(i,l,h)$ 
  - then we don't need a new node
  - ⇒ there exists an isomorphic subtree, return that
- If  $H$  does not contain such a triple  $(i,l,h)$ 
  - then we need to create it and return its index

```
Mk(i,l,h) {  
    if l=h then  
        return l;  
    else if member(H,i,l,h) then  
        return lookup(H,i,l,h);  
    else {  
        u=add(T,i,l,h);  
        insert(H,i,l,h,u);  
        return u;  
    }  
}
```

# Handling ROBDDs 4.

Building an ROBDD: `Build(f)` and `Build'(t,i)` recursive helper function

```
Build(f) {  
  init(T); init(H);  
  return Build'(f,1);  
}
```

Will traverse variables  
recursively

```
Build'(t,i) {  
  if i>n then  
    if t==false then return 0 else return 1  
  else {v0 = Build'(t[0/xi],i+1);  
        v1 = Build'(t[1/xi],i+1);  
        return Mk(i,v0,v1)}  
}
```

Reached a terminal node  
(every variable substituted)

Recursive building;  
Mk() will check  
isomorphic subtrees

# Operations on ROBDDs (cont'd)

- Boolean operators can be evaluated directly on ROBDDs
  - Variables of the functions should be the same in the same order
- **Equivalence** for functions  $f$ ,  $t$  ( $op$  is a Boolean operator):
  - 1)  $f \text{ op } t = (x \rightarrow f_x, f_{\underline{x}}) \text{ op } (x \rightarrow t_x, t_{\underline{x}}) = x \rightarrow (f_x \text{ op } t_x), (f_{\underline{x}} \text{ op } t_{\underline{x}})$
- Additional rules (in case of missing variables due to reduction):
  - 2)  $f \text{ op } t = (x \rightarrow f_x, f_{\underline{x}}) \text{ op } t = x \rightarrow (f_x \text{ op } t), (f_{\underline{x}} \text{ op } t)$
  - 3)  $f \text{ op } t = f \text{ op } (x \rightarrow t_x, t_{\underline{x}}) = x \rightarrow (f \text{ op } t_x), (f \text{ op } t_{\underline{x}})$
- Based on these rules  $App(op, i, j)$  can be defined recursively
  - where  $i, j$ : indices of the root nodes of operands
- Drawback: slow
  - worst-case  $2^n$  exponential

# Accelerated operation

- Let  $G(op,i,j)$  be a cache table that contains the results of  $App(op,i,j)$  (these are nodes)
- The four cases of the algorithm:
  - Both nodes are **terminal**: return a terminal based on the Boolean operation (e.g.  $0 \wedge 1 = 0$ )
  - If the **variable indices** for both operands are **the same**, then call  $App(op,i,j)$  with the **0** branches and with the **1** branches based on **equivalence (1)**
  - If one **variable index is less**, then that node is paired with the **0** and **1** branches of the other node based on **rules (2) or (3)**

# Pseudo-code of the operation

```
Apply(op, f, t) {  
    init(G);  
    return App(op, f, t);  
}
```

```
App(op, u1, u2) {  
    if (G(op, u1, u2) != empty) then return G(op, u1, u2);  
    else if (u1 in {0,1} and u2 in {0,1}) then u = op(u1, u2);  
    else if (var(u1) = var(u2)) then  
        u=Mk(var(u1), App(op, low(u1), low(u2)),  
            App(op, high(u1), high(u2)));  
    else if (var(u1) < var(u2)) then  
        u=Mk(var(u1), App(op, low(u1), u2), App(op, high(u1), u2));  
    else (* if (var(u1) > var(u2)) then *)  
        u=Mk(var(u2), App(op, u1, low(u2)), App(op, u1, high(u2)));  
    G(op, u1, u2)=u;  
    return u;  
}
```

# Example: Performing operation $(f \wedge t)$

# Example: Performing operation $(f \wedge t)$

f

t

# Example: Result of operation $(f \wedge t)$

# Substitute a variable in an ROBDD

Substitute (bind) variables with constants (e.g.  $(\neg x \wedge y)^{[y=1]} = \neg x$ ):

The value of  $x_j$  should be  $b$  in the ROBDD rooted in  $u$

```
Restrict(u, j, b) {  
    return Res(u, j, b);  
}
```

```
Res(u, j, b) {  
    if var(u) > j then return u;  
    else if var(u) < j then  
        return Mk(var(u),  
                  Res(low(u), j, b),  
                  Res(high(u), j, b));  
    else  
        if b=0 then  
            return Res(low(u), j, b)  
        else  
            return Res(high(u), j, b);  
}
```

If we are lower than the variable to substitute, then the original subtree is returned

If we are higher, then we need recursive building

If we are at the variable to substitute, we process only the branch  $b$
